## IV. Using Trilinos in application codes - Part I

- 3 TPETRA Package
- 4 `Tpetra::Map`
- 5 `Tpetra::Vector`
- 6 `Tpetra::MultiVector`
- 7 `Tpetra::CrsMatrix`
- 8 `Tpetra::CrsMatrix` – Matrix assembly
- 9 Matrix-vector multiplication
- 10 `Tpetra::Import` & `Tpetra::Export`

## Scope

Focus on an **introduction to the Tpetra linear algebra package with respect to distributed-memory (MPI) parallelization.**

## Out of the scope

An introduction to all `TRILINOS` packages including **shared-memory (X) parallelization using Kokkos.**

**Before working with Trilinos**, please also take a look at the TEUCHOS package! It provides **many useful tools** and is used all over the TRILINOS code.

- **Memory management** (e.g., Teuchos::RCP **smart pointers** or Teuchos::Array **arrays with additional functionality**)  
*(very helpful to replace many standard C++ data types and containers)*
- **Parameter lists**  
*(very helpful for handling parameters for functions, classes, or whole programs)*
- **Communication** (e.g., Teuchos::Comm)  
*(See [https://docs.trilinos.org/dev/packages/teuchos/doc/html/classTeuchos\\_1\\_1Comm.html](https://docs.trilinos.org/dev/packages/teuchos/doc/html/classTeuchos_1_1Comm.html))*
- **Numerics** (e.g., BLAS and LAPACK wrappers)
- **Output support, exception handling, unit testing support**, and much more ...

→ TEUCHOS Doxygen documentation:

<https://docs.trilinos.org/dev/packages/teuchos/doc/html/>

## Important classes:

`Tpetra::Map`

**Parallel distributions:** Contains information used to distribute vectors, matrices, and other objects

`Tpetra::Vector`

& `Tpetra::MultiVector`

**Distributed sparse vectors:** Provides vector services such as scaling, norms, and dot products.

`Tpetra::Operator`

**Base class for linear operators:** Abstract interface for operators (e.g., matrices and preconditioners).

`Tpetra::RowMatrix`

**Distributed sparse matrices:** An abstract interface for row-distributed sparse matrices; derived from `Tpetra::Operator`.

`Tpetra::CrsMatrix`

**Distributed sparse matrices:** Specific implementation of `Tpetra::RowMatrix`, utilizing compressed row storage (CRS) format

`Tpetra::Import`

& `Tpetra::Export`

**Import/Export classes:** Allow efficient transfer of objects built using one mapping to a new object with a new mapping.

→ TPETRA Doxygen documentation:

<https://docs.trilinos.org/dev/packages/tpetra/doc/html/>

- The parallel linear algebra objects from  $\text{TPETRA}$  are typically **distributed based on the rows**.
- **Example:** Consider the case of a vector  $V \in \mathbb{R}^5$  and a sparse matrix  $A \in \mathbb{R}^{5 \times 5}$

$$V = \begin{bmatrix} v \\ w \\ x \\ y \\ z \end{bmatrix} \quad A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix}$$

distributed among two parallel processes:

$$V = \begin{bmatrix} v \\ w \\ x \\ y \\ z \end{bmatrix} \quad A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix}$$

proc 0

proc 1

- This can be implemented by storing the *local portions of the vector and the matrix*:

$$\begin{array}{ll}
 V_0 = \begin{bmatrix} v \\ x \\ z \end{bmatrix} & A_0 = \begin{bmatrix} a & b & & & \\ & f & g & h & \\ & & & l & m \end{bmatrix} & \text{proc 0} \\
 V_1 = \begin{bmatrix} w \\ y \end{bmatrix} & A_1 = \begin{bmatrix} c & d & e & & \\ & & i & j & k \end{bmatrix} & \text{proc 1}
 \end{array}$$

**Problem:** If only the partitioned data is available on the processes, the global vector  $V$  and matrix  $A$  cannot be restored. In particular, it is not clear where the local rows are located in the global matrix.

- Therefore, we additionally store the **global row indices corresponding to the local rows**, here denoted as  $M_0$  and  $M_1$  (local-to-global map):

$$\begin{array}{lll}
 V_0 = \begin{bmatrix} v \\ x \\ z \end{bmatrix} & A_0 = \begin{bmatrix} a & b & & & \\ & f & g & h & \\ & & & l & m \end{bmatrix} & M_0 = \begin{bmatrix} 0 \\ 2 \\ 4 \end{bmatrix} & \text{proc 0} \\
 V_1 = \begin{bmatrix} w \\ y \end{bmatrix} & A_1 = \begin{bmatrix} c & d & e & & \\ & & i & j & k \end{bmatrix} & M_1 = \begin{bmatrix} 1 \\ 3 \end{bmatrix} & \text{proc 1}
 \end{array}$$

- Using the local-to-global map, the global objects are fully specified. **Process 0:**

$$\begin{array}{lcl}
 V_0 = \begin{bmatrix} v \\ x \\ z \end{bmatrix} & A_0 = \begin{bmatrix} a & b & & & \\ & f & g & h & \\ & & & l & m \end{bmatrix} & M_0 = \begin{bmatrix} 0 \\ 2 \\ 4 \end{bmatrix} \quad \text{proc 0} \\
 \rightarrow V_0 = \begin{bmatrix} v \\ x \\ z \end{bmatrix} & A_0 = \begin{bmatrix} a & b & & & \\ & f & g & h & \\ & & & l & m \end{bmatrix} & 
 \end{array}$$

- Process 1:**

$$\begin{array}{lcl}
 V_1 = \begin{bmatrix} w \\ y \end{bmatrix} & A_1 = \begin{bmatrix} c & d & e & & \\ & i & j & k & \end{bmatrix} & M_1 = \begin{bmatrix} 1 \\ 3 \end{bmatrix} \quad \text{proc 1} \\
 \rightarrow V_1 = \begin{bmatrix} w \\ y \end{bmatrix} & A_1 = \begin{bmatrix} c & d & e & & \\ & i & j & k & \end{bmatrix} & 
 \end{array}$$

- In summary, in addition to the **local portions of the global Tpetra objects**, **local-to-global mappings** are necessary to describe parallel distributed global objects:

$$V = \begin{bmatrix} v \\ w \\ x \\ y \\ z \end{bmatrix} \quad A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix}$$

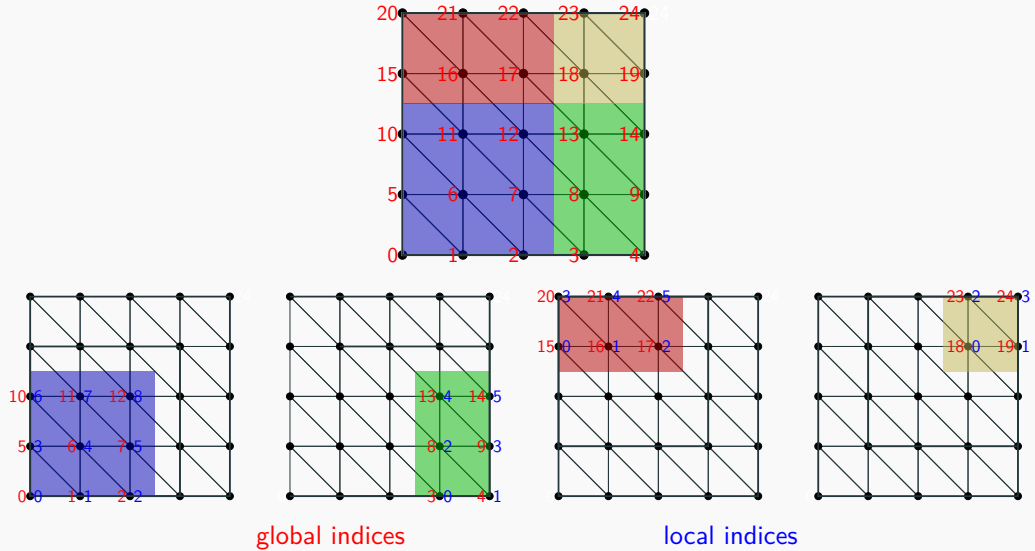

proc 0

proc 1

- The local-to-global mappings are stored in `Tpetra::Map` objects.

See [https://docs.trilinos.org/dev/packages/tpetra/doc/html/classTpetra\\_1\\_1Map.html](https://docs.trilinos.org/dev/packages/tpetra/doc/html/classTpetra_1_1Map.html) for more details.

# Tpetra::Map – Exemplary Map/Distribution for a Mesh

As previously shown, a **parallel distributed vector** (`Tpetra::Vector`) essentially corresponds to

- arrays containing the **local portions of the vectors** (entries) and
- a `Tpetra::Map` storing the **local-to-global mapping**.

## Constructor:

```
Vector ( const Teuchos::RCP< const map_type >& map, /* optional */ )
```

**map:** `Tpetra::Map` object specifying the parallel distribution of the `Tpetra::Vector`. The map also defines the length (local and global) of the vector.

- The `Tpetra::MultiVector` allows for the construction of **multiple vectors with the same parallel distribution**:

$$V = \begin{bmatrix} v_{11} & \dots & v_{1m} \\ v_{21} & \dots & v_{2m} \\ \vdots & \ddots & \vdots \\ v_{(n-1)1} & \dots & v_{(n-1)m} \\ v_{n1} & \dots & v_{nm} \end{bmatrix} \in \mathbb{R}^{n \times m} \quad \text{with } n \gg m$$

- A typical use case would be a **linear equation system with multiple right hand sides**:

$$AX = B$$

with  $A \in \mathbb{R}^{n \times n}$ ,  $X \in \mathbb{R}^{n \times m}$ , and  $B \in \mathbb{R}^{n \times m}$ . Here,  $A$  would typically be a sparse matrix and  $X$  and  $B$  multivectors.

- It can also be used to implement **skinny dense matrices**.

→ Constructing a `Tpetra::MultiVector` requires the number of vectors to be specified.

## Tpetra::CrsMatrix

As previously shown, a **parallel distributed sparse matrix** (`Tpetra::CrsMatrix`) essentially corresponds to

- the **local portions** of the sparse matrix and
- a `Tpetra::Map` storing the **local-to-global mapping** corresponding to the rows.

In the `Tpetra::CrsMatrix`, the local portions of the sparse matrix are stored in *compressed row storage (CRS) format*.

Minimal constructor:

```
CrsMatrix ( const Teuchos::RCP< const map_type > &rowMap ,  
            const size_t maxNumEntriesPerRow , /* optional */ )
```

`rowMap`

Parallel distribution of the rows

`maxNumEntriesPerRow`

Maximum number of nonzero entries per row

- In addition to the row map, which corresponds to the local-to-global mapping of the row indices, e.g.,

$$A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m & o \\ & & & & p & q \end{bmatrix}$$

$$M_0 = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \text{proc 0}$$
$$M_1 = \begin{bmatrix} 2 \\ 3 \end{bmatrix} \quad \text{proc 1}$$
$$M_2 = \begin{bmatrix} 4 \\ 5 \end{bmatrix} \quad \text{proc 2}$$

there is also **local-to-global mapping for the column indices**, the *column map*.

- If the column map is not specified at the construction of the matrix, it can be generated automatically by the Tpetra::CrsMatrix object at a later point.

$$A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m & o \\ & & & & p & q \end{bmatrix}$$

$$M_0 = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \text{proc 0}$$

$$M_1 = \begin{bmatrix} 2 \\ 3 \end{bmatrix} \quad \text{proc 1}$$

$$M_2 = \begin{bmatrix} 4 \\ 5 \end{bmatrix} \quad \text{proc 2}$$

A compatible *column map* corresponding to this *row map* would be:

$$A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m & o \\ & & & & p & q \end{bmatrix}$$

$$\tilde{M}_0 = \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix} \quad \text{proc 0}$$

$$\tilde{M}_1 = \begin{bmatrix} 2 \\ 3 \\ 4 \\ 5 \end{bmatrix} \quad \text{proc 1}$$

$$\tilde{M}_2 = \begin{bmatrix} 3 \\ 4 \\ 5 \end{bmatrix} \quad \text{proc 2}$$

- Column maps are **generally not unique**, as in our example:

$$A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m & o \\ & & & & p & q \end{bmatrix}$$

$$\tilde{M}_0 = \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix}$$

proc 0

$$\tilde{M}_1 = \begin{bmatrix} 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

proc 1

$$\tilde{M}_2 = \begin{bmatrix} 3 \\ 4 \\ 5 \end{bmatrix}$$

proc 2

**Not unique** means that multiple processes share global indices.

- After construction of the matrix, in order to **insert values into the matrix**, the functions `insertLocalValues()` and `insertGlobalValues()` can be used.
- The entries to be inserted in a row are in specified in **sparse format**:

`row` Index of the row.

`cols` Indices of the columns where values should be inserted.

`vals` Values to be inserted.

*(Multiple values inserted at the same location will be added up)*

`insertLocalValues()` All indices have to be local. Furthermore,

- the *column map must be available*, and
- the row must be *owned by the calling MPI rank*.

`insertGlobalValues()` All indices have to be global.

- Rows which are *not owned by the calling MPI rank* are later communicated to the *owning MPI rank*.

- If no column map is specified at construction, only `insertGlobalValues()` can be used. Then, the column map is later built by the `Tpetra::CrsMatrix`.

- When all values have been inserted into the matrix, the assembly is finalized by calling `fillComplete()`. Then:
  - Rows on non-owning MPI ranks are communicated to the owning MPI ranks.
  - The final CSR format of the matrix is computed. In particular, the indices are sorted and multiple values inserted at the same location are added up.
  - Global indices are transformed into local indices. Therefore, a new *column map* may be built.
- Only after calling `fillComplete()` the matrix can be further used, e.g., compute a matrix-vector product.
- In case the *row map* or *column map* (in particular, if it was automatically generated) is needed, it can be obtained using the member functions:
 

<code>getRowMap()</code>	Returns the <i>row map</i> of the <code>Tpetra::CrsMatrix</code>
<code>getColMap()</code>	Returns the <i>columns map</i> of the <code>Tpetra::CrsMatrix</code>
- After calling `fillComplete()`, no new values may be inserted. In order to insert new values, `resumeFill()` has to be called.
- In order to change values at existing locations in the sparsity pattern of the matrix, `replaceLocalValues()` and `replaceGlobalValues()` as well as `sumIntoLocalValues()` and `sumIntoGlobalValues()` may be used.

# Matrix-vector multiplication

- As mentioned earlier, the class `Tpetra::CrsMatrix` is derived from `Tpetra::Operator`. Any `Tpetra::Operator` can be applied to a `Tpetra::Vector` or `Tpetra::MultiVector` resulting in another `Tpetra::Vector` or `Tpetra::MultiVector`, respectively.
- The parallel application of any `Tpetra::Operator` is characterized by two maps, the *domain map* and the *range map*.

**domain map** The map of any vector the operator is applied to.

**range map** The map of the resulting vector.

(Both the domain map and the range map have to be unique!)

- In particular, for a `Tpetra::CrsMatrix`, the following **very general situation**, where the *row map*, *domain map*, and *range map* are all different, is allowed:

$$\begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix}$$

- Performing the **matrix-vector multiplication**

$$\begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix}$$

will obviously **require communication**.

- The corresponding **communication is performed automatically**. However, the *domain map* and *range map* must have already been specified before application to a vector.
- The *domain map* and *range map* can be specified within the `fillComplete()` call.
- If they are not specified, they will automatically be chosen as the *row map* of the matrix:

$$\begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix} \begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \end{bmatrix}$$

**Caution:** In contrast to the *domain map* and *range map*, the *row map* does not have to be unique.

- It is possible to change the parallel distribution of Tpetra objects. For example, from

$$V = \begin{bmatrix} v \\ w \\ x \\ y \\ z \end{bmatrix} \quad A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix} \quad \begin{matrix} M_0 = \begin{bmatrix} 0 \\ 2 \\ 4 \end{bmatrix} \quad \text{proc 0} \\ M_1 = \begin{bmatrix} 1 \\ 3 \end{bmatrix} \quad \text{proc 1} \end{matrix}$$

to

$$V = \begin{bmatrix} v \\ w \\ x \\ y \\ z \end{bmatrix} \quad A = \begin{bmatrix} a & b & & & \\ c & d & e & & \\ & f & g & h & \\ & & i & j & k \\ & & & l & m \end{bmatrix} \quad \begin{matrix} M_0 = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \text{proc 0} \\ M_1 = \begin{bmatrix} 2 \\ 3 \\ 4 \end{bmatrix} \quad \text{proc 1} \end{matrix}$$

- The row maps of the distributions are different. Furthermore, data transfer between the processes is necessary. The data transfer is performed by a `Tpetra::Import` or `Tpetra::Export` object.

- `Tpetra::Import` and `Tpetra::Export` objects are constructed using the `Tpetra::Map` of the original distribution (source map) and the `Tpetra::Map` of the desired distribution (target map):

## Constructors

- `Tpetra::Import`

```
Import ( const Teuchos::RCP< const map_type > &source ,
         const Teuchos::RCP< const map_type > &target );
```

- `Tpetra::Export`

```
Export ( const Teuchos::RCP< const map_type > &source ,
         const Teuchos::RCP< const map_type > &target );
```

- Obviously, the redistribution

involves:

- Sending the global rows 2 and 4 from `proc 0` to `proc 1`
  - Sending the global row 1 from `proc 1` to `proc 0`
- Communication is then performed using the member function

```
Tpetra::DistObject<Packet, LocalOrdinal, GlobalOrdinal, Node>::doExport(
    const SrcDistObject<Packet, LocalOrdinal, GlobalOrdinal, Node> &source,
    const Export<LocalOrdinal, GlobalOrdinal, Node> &exporter,
    const CombineMode CM);
```

for the parallel distributed target object (vector, graph, matrix). The source object is the corresponding parallel distributed map with the original distribution.

*(In the corresponding `doImport()` function, the source and target objects are swapped)*

## Assemble a linear system:

- Complete the app `ex_02_assemble` to assemble a linear system (discretized Laplace operator) in `TPETRA`
- Material: `exercises/ex_02_assemble`
